

THAT WHICH IS CLAIMED IS:

1. A method for processing an interrupt signal using a microprocessor comprising a central processing unit (CPU), an interrupt controller providing an interrupt request signal to the CPU when 5 the interrupt signal is received by the microprocessor, registers having a context stored therein corresponding to a program being executed by the CPU, and a stack for storing the context while an interrupt is being executed, the method comprising:

10 detecting a receipt of the interrupt request signal by the CPU from the interrupt controller;
 storing the context from the registers to the stack;
 verifying that the interrupt request signal 15 is provided to the CPU from the interrupt controller after storing the context to the stack;
 sending an interrupt acknowledge signal and reading and executing a first instruction of an interrupt subroutine using the CPU if the interrupt 20 request signal is provided to the CPU; and
 restoring the stored context from the stack to the registers and returning the CPU to an initial state if the interrupt request signal is not provided to the CPU.

2. The method according to Claim 1 wherein reading and executing the first instruction of the interrupt subroutine comprises reading a data element from an address determined based upon an interrupt 5 vector provided by the interrupt controller, the data

element comprising a read address of the first instruction of the interrupt subroutine.

3. The method according to Claim 1 wherein returning the CPU to the initial state comprises reading and executing an instruction of the program being executed by the CPU when the interrupt request signal was detected.

4. The method according to Claim 1 wherein returning the CPU to the initial state comprises processing a new interrupt if a new interrupt request signal is provided by the interrupt controller.

5. The method according to Claim 1 wherein restoring the stored context from the stack comprises restoring contents of a program counter register.

6. The method according to Claim 5 wherein returning the CPU to the initial state comprises providing the restored contents of the program counter register to an address bus.

7. A method for processing an interrupt request using a microprocessor executing a program, the method comprising:

5 detecting the interrupt request;
 storing contextual data of the program;
 sending an interrupt acknowledge signal;
 verifying that the interrupt request is
 present;

resuming execution of the program if the
10 presence of the interrupt request is not verified; and
switching to an interrupt subroutine if the
presence of the interrupt request is verified.

8. The method according to Claim 7 wherein storing contextual data comprises storing data located in registers of the microprocessor in a random-access memory.

9. The method according to Claim 8 wherein the data stored in the random-access memory are stored into respective original registers before resuming execution of the program.

10. The method according to Claim 9 wherein resuming execution of the program is postponed if a new interrupt is detected after the presence of the interrupt request is not verified; and further 5 comprising processing the new interrupt request.

11. A microprocessor comprising:
registers having a context stored therein;
a stack for storing the context;
an interrupt controller for providing an
interrupt request and an interrupt vector when an
interrupt signal is applied to the microprocessor; and
a CPU for receiving the interrupt request and
the interrupt vector and, upon detection of the

10 storing the context in said stack

verifying that the interrupt request is present after storing the context,

15 sending an interrupt acknowledge signal and reading and executing a first instruction of an interrupt subroutine if the presence of the interrupt request is verified, and
restoring the stored context from said stack and returning the microprocessor to an initial state if the presence of the
20 interrupt request is not verified.

12. The microprocessor according to Claim 11 wherein said CPU reads a data element from an address determined based upon the interrupt vector, the data element comprising a read address of the first
5 instruction of the interrupt subroutine.

13. The microprocessor according to Claim 11 further comprising a program counter register; and wherein said CPU restores contents of said program counter register during restoring of the stored
5 context.

14. The microprocessor according to Claim 13 wherein during returning the microprocessor to the initial state said CPU reads and executes an instruction corresponding to an address in said program
5 counter register.

15. A microprocessor according to Claim 11 wherein during returning the microprocessor to an initial state said CPU processes a new interrupt if a

new interrupt request is provided by said interrupt
5 controller.

16. A microprocessor according to Claim 11
further comprising:

a 16-bit program counter register comprising
two 8-bit registers; and

5 a 16-bit stack pointer register comprising
two 8-bit registers.

17. A microprocessor comprising:

a central processing unit (CPU) for
detecting an interrupt request during
execution of a program,

5 storing contextual data of the program
being executed,

sending an interrupt acknowledge signal
and switching to an interrupt subroutine if
the interrupt request is present after

10 storing the contextual data, and

resuming execution of the program if the
interrupt request is not present after
storing the contextual data.

18. The microprocessor according to Claim 17
further comprising a random-access memory and registers
for storing data elements; and wherein said CPU stores
the contextual data by storing the data elements in
5 said random-access memory.

19. The microprocessor according to Claim 18
wherein said CPU stores the data elements stored in the

random-access memory in respective original registers thereof before resuming execution of the program.

20. The microprocessor according to Claim 17 wherein said CPU processes a new interrupt request if the new interrupt request is present after the interrupt request is not present and before resuming 5 execution of the program.
